Objectives

Design a mechanism that achieve differential privacy by scaling to a metric between distribution.

1. A differentially private bayesian mechanism,
2. Calibrating mechanism noise by the same probabilistic distance we want to measure accuracy with.
3. Applying smooth sensitivity in mechanism to achieve better accuracy.

Figure 1: Hellinger Sensitivity

Bayesian Inference Background

Conjugate prior distribution, $\text{beta}(\alpha, \beta)$, with hyper parameters $\alpha, \beta \in \mathbb{R}^+$;

Observed data set \mathbf{x} : $\mathbf{x} = (x_1, \dots, x_n)$, $x_i \in \{0, 1\}$, $n \in \mathbb{N}$;

Bernoulli likelihood function: $\Pr(\mathbf{x}|\theta) \equiv \theta^{\Delta\alpha}(1-\theta)^{n-\Delta\alpha}$, where $\Delta\alpha = \sum_{i=1}^n x_i$;

Posterior distribution derived: $\Pr(\theta|\mathbf{x}) = \text{beta}(\alpha + \Delta\alpha, \beta + n - \Delta\alpha)$.

Differentially private Bayesian inference

Release a private version of posterior distribution $(\tilde{\alpha}, \tilde{\beta}) = (\alpha + \widetilde{\Delta\alpha}, \beta + n - \widetilde{\Delta\alpha})$.

In a baseline approach, we sample noise from $\text{Lap}(\mu, \nu)$ mechanism, i.e., $\widetilde{\Delta\alpha} \sim \text{Lap}(\Delta\alpha, \frac{2}{\epsilon})$,

Smoothed Hellinger Distance based Exponential Mechanism

Our approach defines the mechanism $\mathcal{M}_{\mathcal{H}}^B$:

Producing an element r in $\mathcal{R}_{\text{post}}$ with: $\Pr_{z \sim \mathcal{M}_{\mathcal{H}}^B} [z = r] = \frac{\exp\left(\frac{-\epsilon \cdot \mathcal{H}(\text{BI}(\mathbf{x}), r)}{2 \cdot S(\mathbf{x})}\right)}{\sum_{r \in \mathcal{R}_{\text{post}}} \exp\left(\frac{-\epsilon \cdot \mathcal{H}(\text{BI}(\mathbf{x}), r)}{2 \cdot S(\mathbf{x})}\right)}$,

(given in input an observations \mathbf{x} , parameters $\epsilon > 0$ and $\delta > 0$).

$\mathcal{R}_{\text{post}}$ is the candidates set defined as

$\mathcal{R}_{\text{post}} \equiv \{\text{beta}(\alpha', \beta') \mid \alpha' = \alpha + \Delta\alpha, \beta' = \beta + n - \Delta\alpha\}$, given the prior distribution $\beta_{\text{prior}} = \text{beta}(\alpha, \beta)$ and observed data set size n .

The scoring function is instantiated by Hellinegr distance between two beta distributions, and

$S(\mathbf{x})$ is the smooth sensitivity computed as: $S(\mathbf{x}) = \max_{\mathbf{x}' \in \{0,1\}^n} \left\{ LS(\mathbf{x}') \cdot e^{-\gamma \cdot d(\mathbf{x}, \mathbf{x}')}\right\}$,

where d : Hamming distance between two datasets,

$LS(\mathbf{x}')$ denotes the local sensitivity at $\text{BI}(\mathbf{x}')$:

$LS(\mathbf{x}) = \max_{\mathbf{x}' \in \mathcal{X}^n: \text{adj}(\mathbf{x}, \mathbf{x}'), r \in \mathcal{R}} |\mathcal{H}(\text{BI}(\mathbf{x}'), r) - \mathcal{H}(\text{BI}(\mathbf{x}), r)|$ and $\gamma = \ln(1 - \frac{\epsilon}{2 \ln(\frac{\delta}{2(n+1)})})$

to ensure the (ϵ, δ) -differentially private.

Some Experimental Results

(a) 2-dimensional, data size $\in [100, 500]$

(b) 3-dimensional, data size $\in [100, 500]$

(c) 4-dimensional, data size $\in [100, 600]$

Figure 2: Increasing data size with unit prior $\text{beta}(1, 1)$, $\text{beta}(1, 1, 1)$ and $\text{beta}(1, 1, 1, 1)$, balanced datasets and parameters $\epsilon = 0.8$ and $\delta = 10^{-8}$

(a) 2-dimensional

(b) 3-dimensional

(c) 4-dimensional

Figure 3: The concrete outputting probabilities under different dimensions with data set of size 600, unit prior $\text{beta}(1, 1)$, $\text{beta}(1, 1, 1)$ and $\text{beta}(1, 1, 1, 1)$, balanced datasets and parameters $\epsilon = 0.8$ and $\delta = 10^{-8}$

Conclusion

- Our the probabiliy measure approach outperforms the ℓ_1 -norm approach when the Laplace noise cannot recognize the data to be protected is histogram and data size grow large.
